PQ30RV1/PQ30RV11/PQ30RV2/PQ30RV21

Variable Output Low Power-Loss Voltage Regulators

■ Features

- Compact resin full-mold package
- Low power-loss (Dropout voltage : MAX.0.5V)
- Variable output voltage (setting range : 1.5 to 30V)
- Built-in output ON/OFF control function

■ Applications

- Power supply for print concentration control of electronic typewriters with display
- Series power supply for motor drives
- Series power supply for VCRs and TVs

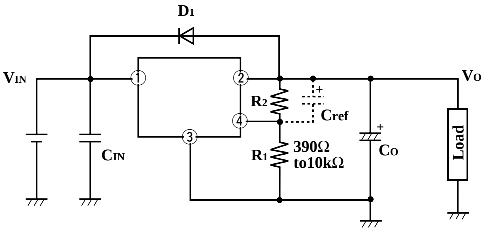
■ Standard Connection



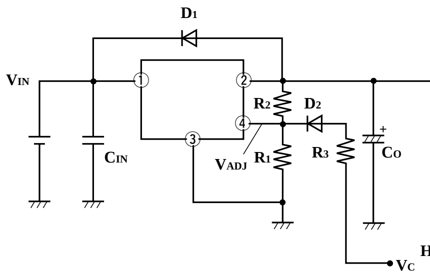
D_1 : This device is necessary to protect the element from damage when reverse voltage may be applied to the regulator in case of input short-circuiting.

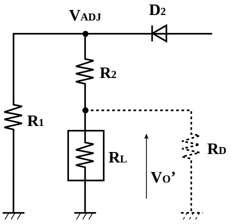
C_{ref} : This device is necessary when it is required to enhance the ripple rejection or to delay the output start-up time(*1).
(*1)Otherwise, it is not necessary.
(Care must be taken since C_{ref} may raise the gain, facilitating oscillation.)
(*1)The output start-up time is proportional to $C_{ref} \times R_2$.

C_{IN}, C_O : Be sure to mount the devices C_{IN} and C_O as close to the device terminal as possible so as to prevent oscillation.
The standard specification of C_{IN} and C_O is 0.33µF and 47µF, respectively. However, ajust them as necessary after checking.

R_1, R_2 : These devices are necessary to set the output voltage. The output voltage V_O is given by the following formula:
$V_O = V_{ref} \times (1+R_2/R_1)$
(V_{ref} is 1.25V TYP)
The standard value of R_1 is 390Ω.But value up 10kΩdoes not cause any trouble.

■ ON/OFF Operation





Equivalent Circuit
in OFF-state

- ON/OFF operation is available by mounting externally D_2 and R_3.
- When V_{ADJ} is forcibly raised above V_{ref} (1.25V TYP) by applying the external signal, the output is turned off (pass transistor of regulator is turned off). When the output is OFF, V_{ADJ} must be higher then V_{ref} MAX., and at the same time must be lower than maximum rating 7V.
  In OFF-state, the load current flows to R_L from V_{ADJ} through R_2. Therefore the value of R_2 must be as high as possible.
- $V_O'=V_{ADJ} \times R_L/(R_L+R_2)$
  occurs at the load. OFF-state equivalent circuit R_1 up to 10Ω is allowed. Select as high value of R_L and R_2 as possible in this range. In some case, as output voltage is getting lower (V_O<1V) , impedance of load resistance rises. In such condition, it is sometime impossible to obtain the minimum value of V_O'. So add the dummy resistance indicated by R_D in the figure to the circuit parallel to the load.

■ An Example of ON/OFF Circuit Using the 1-chip Microcomputer Output Port (PQ30RV1)

<Specification>
Output port of microcomputer
V_{OH} (max) =0.5 V
V_{OH} (min) =2.4 V (I_{OH}=0.2mA)
MAX. rating of I_{OH}=0.5mA
Output should be set as follows.
15.6V R_L=52Ω (I_O=0.3A)

From $V_O=1.25V\ (1+R_2/R_1)$ we get V_O=15.6V.
$R_2/R_1=11.48$
Assuming that V_F(max)=0.8V for D_2 in case of V_{OH}(min)=2.4V, we get $V_{ADJ}=V_{OH}(min)-V_F(max)$=2.4V-0.8V=1.6V. From V_{ref}(max)=1.3V we get R_3=0Ω
If R_1=10kΩ, we get $R_2=11.48 \times R_1$=114.8kΩ and I_{OH} as follows, ingnoring R_L (52Ω) :
$I_{OH}=1.6V \times (R_1+R_2)/R_1 \times R_2$
$=1.6V \times (10k\Omega+114.8k\Omega)/10k\Omega \times 114.8k\Omega=0.17mA$
Hence, I_{OH}<0.2mA. Therefore V_{OH}(min)is ensured.
Next, assuming that V_F(min) =0.5V for D_2 in case of V_{OH}(max), we get:
$I_{OH}=(5V-0.5V)\ (R_1+R_2)/R_1 \times R_2$=0.49mA which is less than the rating.
Figure 1 shows the V_O-V_C characteristics when R_1=10kΩ, R_2=115kΩ, R_3=0Ω, V_{IN}=17V, R_L=52Ω, and D_1=1S2076A (Hitachi).
